Initial Report on Federally Funded Ocean Acidification Research and Monitoring Activities and Progress in Developing a Strategic Plan

Prepared by
Interagency Working Group on Ocean Acidification
Subcommittee on Ocean Science and Technology
Committee on Environment, Natural Resources, and
Sustainability

Report directed by Section 12404(c) of the Federal Ocean Acidification Research and Monitoring Act of 2009 (FOARAM Act)

Issued March 22, 2011

EXECUTIVE OFFICE OF THE PRESIDENT NATIONAL SCIENCE AND TECHNOLOGY COUNCIL

WASHINGTON, D.C. 20502

March 22, 2011

Dear Colleague:

I am pleased to transmit this document, *Initial Report on Federally Funded Ocean Acidification Research and Monitoring Activities and Progress in Developing a Strategic Research Plan*, which summarizes federally funded ocean acidification research and monitoring activities; provides the budgets for these activities; and describes progress toward the development of a strategic research plan for Federal research and monitoring of ocean acidification.

In March 2009, Congress passed the Federal Ocean Acidification Research and Monitoring Act of 2009 (FOARAM Act). The authorization of the FOARAM Act acknowledged the importance of the observed decrease in pH of the Earth's oceans and the need to address this issue. The FOARAM Act also called for the establishment of an Interagency Working Group on Ocean Acidification, to be chartered through the Joint Subcommittee on Ocean Science and Technology of the National Science and Technology Council. This document constitutes the initial report of the Working Group. It will be followed by a strategic plan for Federal research and monitoring of ocean acidification which will provide a roadmap for assessing the impacts of ocean acidification on marine organisms and marine ecosystems and for developing adaptation and mitigation strategies to conserve those organisms and ecosystems.

As was documented in a recent National Research Council report, *Ocean Acidification: A National Strategy to Meet the Challenges of a Changing Ocean*, the long-term consequences of ocean acidification are not known but are likely to include serious impacts on ecosystems and the services those systems provide to society. Therefore, it is critical that we proceed towards developing a coordinated program to understand ocean acidification and its impacts. This inventory of Federal activities is an important step in this process. I hope Congress and other parties interested in ocean acidification will find its content of great value.

Sincerely,

John P. Holdren

John P. Holder

Assistant to the President for Science and Technology Director, Office of Science and Technology Policy

Executive Summary
Introduction
Section 1. Monitoring of ocean chemistry and biological impacts associated with ocean acidification at selected coastal and open-ocean monitoring stations, including satellite-based monitoring to characterize marine ecosystems, changes in marine productivity, and changes in ocean chemistry
Section 2. Research to understand the species-specific physiological responses of marine organisms to ocean acidification, impacts on marine food webs of ocean acidification, and develop environmental and ecological indices that track marine ecosystem responses to ocean acidification
Section 3. Modeling to predict changes in the ocean carbon cycle as a function of carbon dioxide and atmosphere-induced changes in temperature, ocean circulation, biogeochemistry, ecosystem and terrestrial input, and modeling to determine impacts on marine ecosystems and individual marine organisms
Section 4. Technology development and standardization of carbonate chemistry measurements on moorings and autonomous floats
Section 5. Assessment of socioeconomic impacts of ocean acidification and development of adaptation and mitigation strategies to conserve marine organisms and marine ecosystems 8
Section 6. Education/Outreach on ocean acidification
Progress in Developing the Strategic Research Plan for Ocean Acidification
Appendix 1. Summary of Federally Funded Ocean Acidification Research and Monitoring Activities
Appendix 2. Strategic Research Plan for Ocean Acidification Outline

Executive Summary

This document responds to the Federal Ocean Acidification Research and Monitoring Act of 2009 (FOARAM Act). The FOARAM Act specifies that the Joint Subcommittee on Science and Technology (JSOST) shall transmit an initial report to the Committee on Commerce, Science, and Transportation of the Senate and the Committee on Science and Technology and the Committee on Natural Resources of the House of Representatives that:

- (A) includes a summary of federally funded ocean acidification research and monitoring activities, including the budget for each of these activities; and
- (B) describes the progress in developing a strategic research plan required under section 12405 of this subtitle.

In this initial report, Federal agency activities related to ocean acidification are summarized for fiscal years 2008 and 2009 (FY 2008-09). Activities are classified as having either a primary focus on ocean acidification or being "contributing" activities, in that they were designed for other purposes but clearly provide information useful for understanding ocean acidification. In 2008 Federal agencies supported approximately \$6.8 million of activities with a primary focus on ocean acidification and an additional \$22.7 million for contributing studies. In 2009 funding was approximately \$10.9 million for primary and \$21.3 million for contributing studies. Activities included monitoring of ocean chemistry and biological impacts, research to understand species-specific and ecosystem responses to ocean acidification, biogeochemical and ecosystem modeling, technology development, and education/outreach activities. A majority of the activities with a primary focus on ocean acidification were directed at understanding species and ecosystem responses, while the major activities for contributing studies were monitoring, modeling, and studies of species and ecosystem responses. In FY 2008-09 no Federal activities supported the assessment of socioeconomic impacts of ocean acidification.

A Strategic Research Plan for Ocean Acidification, as required by the FOARAM Act, is under development, with delivery anticipated in 2011. JSOST (recently renamed the Subcommittee on Ocean Science and Technology or SOST) is conferring with domestic and international scientific advisory groups concerned with ocean acidification to ensure that the plan is well coordinated with non-government scientists, and is informed by the latest scientific advice.

Introduction

The Federal Ocean Acidification Research and Monitoring Act of 2009 (FOARAM Act) directed the Joint Subcommittee on Science and Technology¹ (SOST) to create an Interagency Working Group on Ocean Acidification (IWG-OA). Section 12404(c) of the FOARAM Act further specifies that the SOST will transmit a report to the Committee on Commerce, Science, and Transportation of the Senate and the Committee on Science and Technology and the Committee on Natural Resources of the House of Representatives that:

- (A) includes a summary of federally funded ocean acidification research and monitoring activities, including the budget for each of these activities; and
- (B) describes the progress in developing a strategic research plan required under section 12405 of this subtitle.

This constitutes the initial report of the SOST IWG-OA. The IWG-OA was chartered by SOST in October 2009 and includes representatives from the National Oceanic and Atmospheric Administration (NOAA), National Aeronautics and Space Administration (NASA), National Science Foundation (NSF), U.S. Geological Survey (USGS), Environmental Protection Agency (EPA), Minerals Management Service (MMS, which has since been renamed the Bureau of Ocean Energy Management, Regulation and Enforcement [BOEMRE]), Department of State (DOS) and U.S. Fish and Wildlife Service (USFWS). This includes two ex officio members representing the former Subcommittee on Integrated Management of Ocean Resources (SIMOR). NOAA chairs the group, with vice-Chairs from NSF and NASA. The group meets regularly to coordinate ocean acidification activities across the Federal government and has made significant progress toward meeting the goals of the FOARAM Act.

The report is organized into six main sections corresponding to the categories of information required in the strategic plan for ocean acidification research and monitoring. Each section contains an overview of the activities conducted within that category by Federal agencies in FY 2008-09. Appendix 1 provides a summary of individual agency ocean acidification research and monitoring activities, including the budget for each of these activities. In Appendix 1, activities are classified as having a primary focus on ocean acidification or as "contributing" activities designed for other purposes but clearly providing information useful for understanding ocean acidification.

Section 1. Monitoring of ocean chemistry and biological impacts associated with ocean acidification at selected coastal and open-ocean monitoring stations, including satellite-based monitoring to characterize marine ecosystems, changes in marine productivity, and changes in ocean chemistry.

In order to understand the progress of ocean acidification in open-ocean and coastal environments and its impacts on marine ecosystems it will be necessary to develop a coordinated multidisciplinary approach to observations and modelling. This approach, in turn, will be fundamental for establishing a successful research strategy relating to ocean acidification and for facilitating our ability to predict and respond to future impacts on marine biota, ecosystem processes, biogeochemistry, and climate feedbacks. In 2008 and 2009 EPA, MMS², NASA,

² Renamed Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) in June 2010.

¹ Renamed as the Subcommittee on Ocean Science and Technology (SOST) on Dec. 2, 2010.

NOAA, NSF, and USGS all supported studies that were focused on monitoring ocean chemistry or biological impacts associated with ocean acidification, or studies that had a slightly different focus but contributed to these goals. Approximately \$1,426K was spent on monitoring directly related to ocean acidification in 2008, and \$1,289K in 2009. Approximately \$12,501K was spent on activities that were not specifically termed ocean acidification studies but contributed to monitoring ocean acidification in 2008, and \$10,164K in 2009.

The existing global oceanic carbon observatory network of repeat hydrographic surveys, time-series stations, and volunteer observing ships in the Atlantic, Pacific, and Indian Oceans supported by NSF and NOAA has documented many aspects of carbonate chemistry central to the process of ocean acidification in open-ocean and coastal waters. Indeed, much of our present understanding of the long-term changes in the carbonate system is derived from such repeat surveys and time series measurements over the past two decades. From these studies it has been determined that the pH of ocean surface waters has already decreased by about 0.1 since the industrial era began, while a decrease of ~ 0.0018 per year has been observed over the last quarter century at several open-ocean time-series sites. In addition, many ecosystem monitoring and assessment studies provide valuable information for examining the impacts of ocean acidification.

Numerous studies were conducted in FY 2008-09 in which one of the primary goals was associated with monitoring ocean acidification. Large-scale studies of carbonate chemistry in the Pacific and Indian Oceans, supported by NOAA and NSF, revealed basin-wide changes in carbon chemistry and pH. MMS supported a biogeochemical assessment of the North Aleutian Basin ecosystem while joint work by NOAA and USGS is providing an experimental ocean acidification product that provides regional maps of a variety of ocean acidification-relevant chemical parameters for the Greater Caribbean region. In addition, USGS studies are providing information regarding ocean acidification impacts on marine ecosystems, productivity, and changes in ocean chemistry in coral reef communities and Florida shelf ecosystems.

Contributing activities included various monitoring and assessment studies, as well as basic research, such as: studies of coral reefs where the results of studies will contribute to the understanding of the affects of ocean acidification on these ecosystems (EPA, MMS, USFWS, NSF); examining the food web and chemical parameters in the Chukchi Sea (MMS); global scale assessments of primary production and its controls, air-sea gas exchange, and carbon cycling (NASA); ocean carbon inventory, global ocean carbon dioxide (CO₂) flux, world ocean circulation experiment, and joint global ocean flux study analysis/reanalysis, quantification of air-sea CO₂ fluxes, and coastal CO₂ measurements for the North American Carbon Program (NOAA); and monitoring of species, ecosystem productivity, and carbon system measurements (NSF).

Section 2. Research to understand the species-specific physiological responses of marine organisms to ocean acidification, impacts on marine food webs of ocean acidification, and to develop environmental and ecological indices that track marine ecosystem responses to ocean acidification.

Marine biological processes can be directly impacted by ocean acidification because of changes in pH, or changes in the concentrations of dissolved CO₂, bicarbonate ion, or carbonate ion. Virtually every major biological function has been shown to respond to these chemical

changes in seawater, including rates of photosynthesis, respiration, growth, calcification, reproduction, and recruitment. In FY 2008-09, NSF, NOAA, USGS, NASA, and EPA were beginning to address some of the pressing issues of organism response to ocean acidification. Approximately \$4,260K was spent on activities directly related to ocean acidification impacts research in 2008, and \$6,366K in 2009. Approximately \$4,991K was spent on activities that were not specifically termed ocean acidification studies, but contributed to ocean acidification impacts research in 2008, and \$4,366K in 2009.

Biology of impacted species

Federal agency activities for FY 2008-09 concerning how ocean acidification affects calcification and other physiological processes were diverse, spanning molecular to physiological functions, including impacts on growth, reproduction, and survival.

Diverse scientific studies supported by NSF measured the effects of changing seawater pH on coral and algal/anemone symbioses, pteropod physiology and gene expression, and shell dissolution in mollusks; gene expression under pH stress, with and without added temperature stress; evolution and pH changes in coccolithophorids; pH impacts on benthic and planktonic foraminifera; and physiology of coral reef larvae with changing pH.

NOAA supported preliminary laboratory and *in situ* experiments using king crab species, shellfish, and krill to test hypotheses related to the direct effects of decreased pH and undersaturation of calcium carbonate in seawater. EPA also supported studies in 2008 that examined the impacts of ocean acidification on individual species.

USGS supported studies involving the effects of ocean acidification on coral health and coral reef degradation, as well as monitoring of coralline algae that form "crusts" of calcium carbonate. Preliminary studies on the effects of lowered pH and higher carbon dioxide values in seawater on photosynthesis and respiration of different tropical and subtropical benthic organisms were also started. Collaborative research between MMS, NOAA, and USGS focused on deep-water coral communities, their ecology, and the microbial communities associated with them.

Ecosystems and Foodwebs

Marine food webs can be complex, and changes in one or more key species can have serious repercussions. Because ocean acidification has the potential to affect key species, it has the potential to alter marine foodwebs in fundamental ways. Further, in some communities, particularly those populated by bottom dwellers, decreases in calcium carbonate production alter the structural fabric of the ecosystem by affecting hard-bottom habitats. Many marine plants and animals depend on the structural habitat provided by corals and other associated organisms in both tropical and cold-water systems. Oyster banks, clam beds, etc. may also be affected by substrate changes associated with decreased carbonate production.

NSF sponsored ocean acidification research in differing physical and geographic environments, comparing open ocean and estuarine "foundation" species in upwelling environments; studying the ecological dynamics of coccolithophorids in the South Atlantic; documenting effects of ocean acidification on nutrient availability and requirements by phytoplankton; and investigating the primary production of coral reefs. Research projects on population dynamics of viruses and coccolithophorids in changing pH; aquatic plant-induced changes in pH, and invertebrate responses and disease resistance in corals in decreased pH environments were also supported.

NOAA scientists have adapted food web models from Puget Sound and the California Current to predict how these ecosystems may respond to future ocean acidification.

NASA studies using remote sensing to identify algal functional groups and their global phenology and to link them to biogeographic provinces were ongoing in 2009. In addition, the identification and development of proxies from satellite data—i.e., indicators of ocean acidification—and improved interpretation of fluorescence signals observable from space or from *in situ* platforms such as underwater gliders, were supported. These efforts provide the foundation to observe physiological processes such as photosynthesis, evaluate phytoplankton health, and provide global datasets for modeling efforts that include ocean acidification.

Calcification processes

Changes in the carbonate ion concentration in seawater affect the "saturation state" of the various calcium carbonate minerals that are used by marine organisms to produce their shells or skeletons. The carbonate ion concentration decreases dramatically with ocean acidification – by 30 percent once the atmospheric CO₂ concentration is twice the preindustrial level. This decreased availability of carbonate ions will limit shell and skeletal formation of many organisms, including corals, shellfish, sea urchins, and some algae.

NSF supported fundamental research to evaluate the solubility of calcite produced by living organisms. Both precipitation and dissolution processes were being evaluated based on solubility. NSF also supported research on coral reef and foraminifera calcification rates and productivity, as well as developing geochemically novel ways to estimate coral reef calcification rates. The BEACON project (BErmuda ocean Acidification and COral reef investigation) seeks understanding of the consequences of ocean acidification on the process of calcification and calcium carbonate production at three different spatial scales, including: (1) individual coral colonies; (2) local reef communities; and (3) regional coral reef ecosystems.

In FY 2008-09 ocean acidification process studies within the USGS included monitoring tropical coral reef calcification and dissolution rates, from the community level to the individual organism level. Support was also provided to study the effects of lowered pH and higher CO_2 values on a group of shell-forming, bottom-dwelling organisms in the tropics and subtropics known as sediment producers.

Other marine chemical and physical attributes

The major nutrient cycles in the ocean, which include geological, chemical, physical, and biological processes, determine the availability of nutrients that support all ocean life, as well as the ability of the oceans to sequester CO₂ from the atmosphere. Ocean acidification has the potential to alter both chemical and biological processes that will affect nutrient and carbon cycles, such as by altering the rate of nitrogen fixation by certain marine cyanobacteria.

In 2009 NSF supported the documentation and understanding of how ocean acidification may affect the formation and sinking of organic and inorganic particles within the water column.

USGS supported studies that evaluated coastal carbon fluxes and submarine groundwater discharges to coral reefs and provided an understanding of related dynamics, which would be additional to the stresses of ocean acidification.

The record of the Earth system history regarding ocean acidification

USGS supported studies in FY 2008-09 that compared historic calcification rates with current rates, with the goal of modeling future biogenic calcification rates. In 2009, USGS

initiated synthesis of historical physical and chemical records at shellfish bed sites within Florida to provide regional view of ocean acidification, while NSF sponsored studies to examine ocean acidification in the geologic record.

NSF and USGS supported development of the use of boron isotopes and their ratio to calcium as a proxy for determining seawater pH, which can then be applied to samples from marine sediments, drill sections from coral reefs, and preserved exoskeletons of gastropods to ascertain environmental conditions in Earth system history. The method has the potential to reflect glacial/interglacial changes of surface seawater pH and atmospheric CO₂ levels.

Section 3. Modeling to predict changes in the ocean carbon cycle as a function of carbon dioxide and atmosphere-induced changes in temperature, ocean circulation, biogeochemistry, ecosystem and terrestrial input, and modeling to determine impacts on marine ecosystems and individual marine organisms.

There were a wide variety of activities during FY 2008-09 within the USGS and NASA that were associated with modeling the marine carbon cycle, although most were not explicitly directed towards ocean acidification. Approximately \$457K was spent on activities directly related to ocean acidification modeling in 2008, and \$162K in 2009. Approximately \$4,658K was spent on activities that were not specifically termed ocean acidification studies but contributed to ocean acidification modeling in 2008, and \$5,205K in 2009.

These latter modeling efforts could likely support ocean acidification understanding through the improved depiction of land-air-sea carbon coupling, understanding carbon fluxes in hydrologic and geologic processes, and defining spatial distributions and fluxes of carbon (i.e., sources and sinks of carbon), production of CO₂ from photosynthesis and respiration, and oceanic carbon cycling. Further, modeling linkages between solubility of nutrients, and carbon sources and sinks, will likely assist in improving future modeling efforts of ocean acidification.

In FY 2008-09, NASA supported modeling of ocean acidification within the greater Caribbean in which seawater carbonate system data acquired from ships of opportunity were used to refine algorithms derived from satellite data. These algorithms are being used to compute saturation state and other carbon parameters. USGS is supporting modeling of historical and future changes in ocean carbon cycle, through the use of boron as a proxy on coral cores. These data are being used to model ecosystem change over historic and geologic time. EPA also supported modeling efforts in 2008, with a focus on addressing the ecological and biological impacts of ocean acidification.

Section 4. Technology development and standardization of carbonate chemistry measurements on moorings and autonomous floats.

Research needs and priorities stated in the FOARAM Act, in agency planning, and in the 2010 National Research Council report, *Ocean Acidification: A National Strategy to Meet the Challenges of a Changing Ocean*, point to the necessity of improved instrumentation, sensors, and methods to support long-term observations, systematic ocean surveys, and the development of experimental systems to investigate organism and ecosystem responses to ocean acidification. Approximately \$480K was spent on activities directly related to technology development for ocean acidification in 2008, and \$1,245K in 2009. Approximately \$419K was spent on activities

that were not specifically termed ocean acidification studies but contributed to ocean acidification technology development in 2008, and \$745K in 2009.

USGS, cooperating with NOAA and universities, supported the refinement and standardization of methods measuring carbon parameters and calcification in coral reef systems as part of efforts to understand the metabolic function of reef systems. USGS has also supported the development of flow-through systems for the rapid measurement of CO₂ levels in water, which will serve both marine and freshwater uses.

NOAA ocean acidification technology developments in FY 2008-09 were focused on coral reef and open ocean systems. La Parguera, Puerto Rico, is the primary site for the coral reef technology development as it is the location of the Atlantic Ocean Acidification Test-bed. This work involves the Atlantic Meteorological and Oceanographic Laboratory, the University of Miami, Pacific Marine Environmental Laboratory and the University of Puerto Rico. Specific technology developments have included a moored autonomous buoy deployed on the fore-reef, providing continuous measurements of near-reef CO₂ levels (both air and sea surface), temperature, and salinity. This test-bed serves as a nexus of Federal agency and academic monitoring and research activities related to ocean acidification and coral reefs within the region. It complements continuous meteorological and oceanographic measurements (e.g., from NOAA's Integrated Coral Observing Network/Coral Reef Early Warning System); weekly geochemical surveys on the reef; and the NOAA, University of Miami, Columbia University, and USGS testing of a unique benthic flux instrument capable of rapidly determining reef metabolic activity.

A small-craft CO₂ analyzer prototype has been developed and deployed to test the value of rapid spatial surveys across the broader reef system. A successful and robust mobile system will be used to establish the broader carbonate system chemistry dynamics across reef systems, and also will assist in identifying sites for future mooring deployments.

With regard to open ocean systems, NOAA and NSF collaborated to develop a deep water mooring in the Gulf of Alaska (Station Papa; 50°N, 145°W) capable of making high frequency measurements of both CO₂ and pH in surface waters. The measurement of two carbon parameters is required to fully understand the chemical changes of ocean acidification. The Papa mooring was the first long-term mooring to transmit two carbon measurements (CO₂ and pH) back to the laboratory in near realtime. It was the prototype mooring for NOAA's proposed Ocean Acidification monitoring system.

NSF technology and methods development has been multifold. An exploratory research grant to California State University, San Marcos, supported the rapid development of a new method to quantify calcification rates in planktonic foraminifera. Planktonic foraminifera comprise a major group of biogenic carbonate producers in the world's oceans, contributing an estimated 25 percent to 65 percent of the total deep-marine calcite budget. Direct quantitative measurement of calcification rates in planktonic foraminifera is necessary for determination of calcium carbonate production rates—a key component of the global ocean calcium carbonate budget.

NSF is supporting the University of South Florida to develop a new method to directly determine carbonate ion concentrations in the laboratory, shipboard, or *in situ*. The method, if successful, will obtain carbonate ion concentrations with ultraviolet spectroscopic observations of lead absorbance spectra by comparing the relative concentrations of lead carbonate and an ensemble of lead chloride complexes, which change in response to varying concentrations of dissolved carbonate.

The standard method for measuring coral reef calcification requires knowledge of the alkalinity differences between reef water and the offshore source water, and the residence time of water over the reef. This is expensive and time-consuming. With NSF support, two researchers at the University of Miami are testing a novel method that uses a simple set of inexpensive instruments and an isotope of beryllium to estimate the residence time. The team will use the method to determine how calcification rates vary spatially and temporally at three well-studied reef systems in the Caribbean and Western Atlantic.

A new approach to measure calcification at the reef scale rather than by small scale incubations with individual organisms is being developed by researchers at Stanford University. During four field seasons at Heron Island Marine Station, located on the Great Barrier Reef, the NSF-funded researchers are making the first simultaneous and *in situ* measurements of Net Community Production/Respiration and Net Community Calcification/Dissolution on a large intact coral reef tract by determining water-column inorganic carbon-system properties along the boundaries of a 3-dimensional control volume.

NASA has supported the development, assessment, and commercialization of a biogeochemical profiling float for ocean carbon studies. The float is designed to incorporate a suite of instruments to remotely quantify components of the carbon cycle, such as primary production, and should serve as a platform for new sensors of the dissolved-carbonate system.

Section 5. Assessment of socioeconomic impacts of ocean acidification and development of adaptation and mitigation strategies to conserve marine organisms and marine ecosystems.

There were no agency activities addressing these issues in 2008 or 2009.

Section 6. Education/Outreach on ocean acidification.

One important aspect of tackling the problem of ocean acidification is the engagement and education of stakeholders and the public through such methods as websites, workshops, and publications. Workshops and special sessions at professional meetings have been conducted to engage the scientific community and provide input for planning strategies over the past several years. Approximately \$200K was spent on activities directly related to ocean acidification outreach in 2008, and \$1,846K in 2009. Approximately \$100K was spent on activities that were not specifically termed ocean acidification studies but contributed to ocean acidification outreach in 2008, and \$809K in 2009.

The State Department has supported various international activities relevant to ocean acidification. These include the development and adoption of the Manado Ocean Declaration, which focuses on the critical linkages between oceans and climate changes and addresses the effects of climate change, including ocean acidification, on marine ecosystems and living resources. In order to promote greater understanding of the impacts of ocean acidification on the marine environment, the United States hosted side events at the United Nations Climate Change Conference in Copenhagen and the 2009 Pacific Regional Environment Program meeting. The United States also supported language recognizing the importance of improving understanding of the impact of climate change on the oceans in the 2009 United Nations resolution 64/71 on oceans and the law of the sea.

NSF, NASA, and NOAA have jointly supported the Ocean Biology and Biogeochemistry project office that has actively engaged the U.S. science community via workshops, acidification courses and preparation of laboratory outreach kits for teachers. The project's ocean acidification website tracks worldwide research activities and publications. The three agencies, along with USGS, also jointly supported a National Research Council study that produced the 2010 report, *Ocean Acidification: A National Strategy to Meet the Challenges of a Changing Ocean*. In addition, NSF, NASA, and NOAA recently sponsored a special issue of Oceanography, the flagship magazine of the Oceanography Society, which included 16 articles on ocean acidification written by leading scientists from around the world.

NOAA has prepared a fact sheet for the public and is hosting a website that serves as an information resource for research activities occurring both in the United States and throughout the world. In 2009 NOAA's National Ocean Service education team and the NOAA Coral Reef Conservation Program developed and implemented a symposium at the National Science Teachers Association National Conference in New Orleans, as well as a follow up Web Seminar that focused on coral ecosystems, climate change, and ocean acidification. The National Marine Educators Association published a special issue on ocean acidification that included a lesson plan for teachers about ocean acidification based on a study jointly sponsored by MMS and NOAA on deepwater corals. The same MMS/NOAA joint study, *Lophelia II 2009: Deepwater Coral Expedition: Reefs, Rigs, and Wrecks*, and outreach materials are available on NOAA's Ocean Exploration website. NOAA's Office of Ocean Exploration also features other outreach materials including a keynote address by a NOAA senior scientist, leader's guide, and lesson plans.

The USGS presents research activities and findings through its website, particularly the site's Sound Waves newsletter, and other outreach mechanisms.

Progress in Developing the Strategic Research Plan for Ocean Acidification

The IWG-OA is in the process of developing the Strategic Research Plan for Ocean Acidification as required by the FOARAM Act. A comprehensive outline has been developed that addresses the contents of the plan specified in Sec. 12405 (Appendix 2). Federal agencies, along with academic and international partners, are conducting work in almost every topical area identified in Section 12405. The IWG-OA has identified all ongoing ocean acidification activities (Appendix 1) and is working with agency scientists and managers to coordinate future work. The IWG-OA is also working with domestic and international scientific advisory groups concerned with ocean acidification to ensure that the plan is well coordinated with nongovernment scientists and is informed by the latest scientific advice on ocean acidification. The IWG-OA anticipates delivering the plan in 2011.

Outline for Strategic Research Plan for Ocean Acidification

Executive Summary

Introduction and Background

What is ocean acidification

Overview of themes in the strategic research plan

Existing reports that inform this strategy

Ocean Carbon and Biogeochemistry report - 2009

National Research Council report – 2010

USGS/NSF/NOAA Coral Reef Report – 2008

Royal Society Report – 2005

2nd High CO₂ World Symposium

OceanOBS'09 community white papers

Legislative Mandate and Report Process

FOARAM Act details. Plan for next 10 years of research.

Process – publish in the Federal Register

Monitoring of Ocean Chemistry and Biological Impacts (Theme 1)

Existing monitoring and gap analysis

Measurement requirements

Strategy for an observational network for ocean acidification

Repeat surveys of chemical and biological properties

Time-series measurements at fixed stations and on floats and gliders

Remote sensing

Research to Understand Responses to Ocean Acidification (Theme 2)

Experimental best practices for assessing species specific impacts in the laboratory and field

Effects on calcification and other physiological processes

Impacts on growth, reproduction, survival

Cumulative or synergistic effects of ocean acidification with other stressors

Modeling to Predict Changes in the Ocean Carbon Cycle and Impacts on Marine **Ecosystems and Organisms (Theme 3)**

General circulation models incorporating carbonate system parameters and carbon cycling

Capacity for regional downscaling, e.g. Arctic

Modeling ecosystem effects of ocean acidification, including habitat shifts and invasions

Technology Development and Standardization of Measurements (Theme 4)

Sensors: current status and future needs

Sustained calibration and validation activities

Best practices

Assessment of Socioeconomic Impacts and Development of Strategies to conserve Marine Organisms and Ecosystems (Theme 5)

Socio-economic or integrated assessment models Impact on food security Mitigation and adaptation strategies

Education/Outreach and Engagement Strategy on Ocean Acidification (Theme 6)

Education, outreach, and communications International engagement strategy

Synthesis of Data and Information Products (Theme 7)

Integration across climate, biogeochemical, and biological datasets Workshops and synthesis meetings

Budget Requirements by Agency

Appendix I: Agency Programs Involved in Ocean Acidification Research

Appendix II: Case Studies – Regional Approaches to Ocean Acidification Monitoring and Research
